Methods

Data Cleaning

```r
hate_df =
  read_csv("./data/HateCrimes.csv") %>%
  mutate(
    state = as.factor(state),
    unemployment = as.factor(unemployment),
    urbanization = as.factor(urbanization),
    hate_crimes_per_100k_splc = as.numeric(hate_crimes_per_100k_splc)
  )
```

Descriptive Statistics

```r
# Table labels
my_labels =
  list(
    unemployment = "Unemployment",
    urbanization = "Urbanization",
    median_household_income = "Median Household Income",
    perc_population_with_high_school_degree = "Percent with HS Degree",
    perc_non_citizen = "Percent Non-Citizen",
    gini_index = "Gini Index",
    perc_non_white = "Percent Non-White",
    hate_crimes_per_100k_splc = "Hate Crimes per 100k"
)

# Table controls
my_controls = tableby.control(
  total = F,
  test = F,
  numeric.stats = c("N", "meansd", "medianq1q3", "range", "Nmiss2"),
  cat.stats = c("N", "countpct"),
  stats.labels = list(
    meansd = "Mean (SD)",
    medianq1q3 = "Median (Q1, Q3)",
    range = "Min - Max",
    Nmiss2 = "Missing",
    countpct = "N (%)",
    N = "N"
    )
  )

# Generate table
descriptive_tab =

## |-  Missing               |                 4                  |
```

As a note, I didn't include the "states" variable as the output was huge and not that helpful. Suggest we include a note somewhere that data from 50 states + Washington, DC.

Distribution of Outcome Data

Histogram of raw outcome data (hate crimes per 100k).

```
hate_df %>%
  ggplot(aes(x = hate_crimes_per_100k_splc, y = ..density..)) +
  geom_histogram(bins = 11) +
  geom_density(alpha = 0.2, color = "blue") +
  labs(
    x = "Hate Crimes per 100k",
    y = "Density"
  )
```
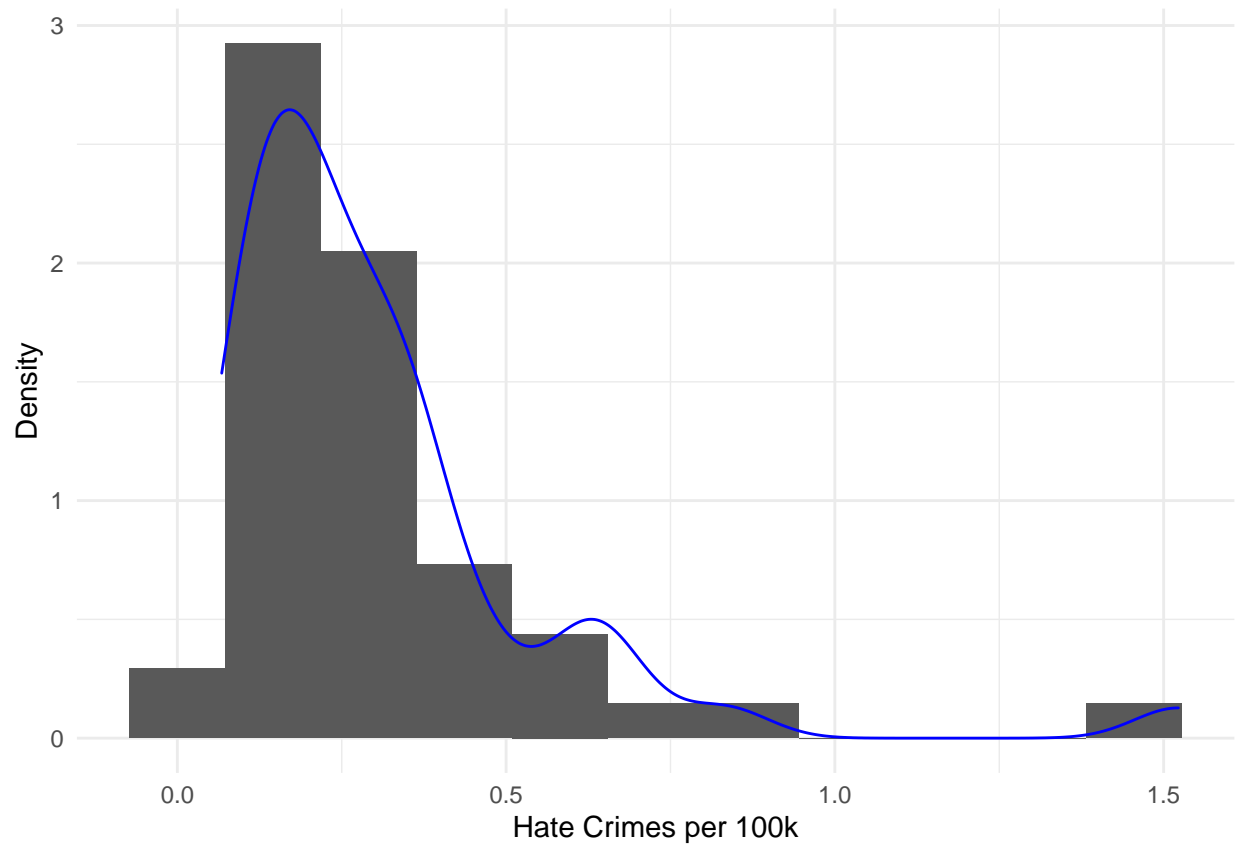

These data look skewed :(

Histogram of log-transformed outcome data (hate crimes per 100k).
```r
hate_df %>%
  ggplot(aes(x = log(hate_crimes_per_100k_splc), y = ..density..)) +
  geom_histogram(bins = 11) +
  geom_density(alpha = 0.2, color = "blue") +
  labs(
    x = "Hate Crimes per 100k (Log Scale)",
    y = "Density"
  )
```

Looks better!

Box plot of the (raw) outcome data.

```r
hate_df %>%
  ggplot(aes(y = hate_crimes_per_100k_splc)) +
  geom_boxplot() +
  labs(
    y = "Hate Crimes per 100k"
  ) +
  theme(
    axis.text.x = element_blank(),
    axis.ticks.x = element_blank()
    )
```

Just based on the box plot, it looks like there are two states with potential usually high rates (Washington, DC and Oregon).

Examining Potential Multicollinearity

```r
hate_df %>%
  select(
    hate_crimes_per_100k_splc,
    median_household_income,
    perc_population_with_high_school_degree,
    perc_non_citizen,
    gini_index,
    perc_non_white
    ) %>%
  cor(use = "complete.obs") %>% # Ignoring NA values
  round(., 2)
```

```
##                                         hate_crimes_per_100k_splc

```

Based on this output, the following pairs of variables have a correlation of 60% or higher:

- Percentage non-citizens & percentage non-white (0.75)

- Median household income & percentage of population with a high school degree (0.65)

```r
hate_df %>%
  select(
    hate_crimes_per_100k_splc,
    median_household_income,
    perc_population_with_high_school_degree,
    perc_non_citizen,
    gini_index,
    perc_non_white
    ) %>%
  pairs()
```
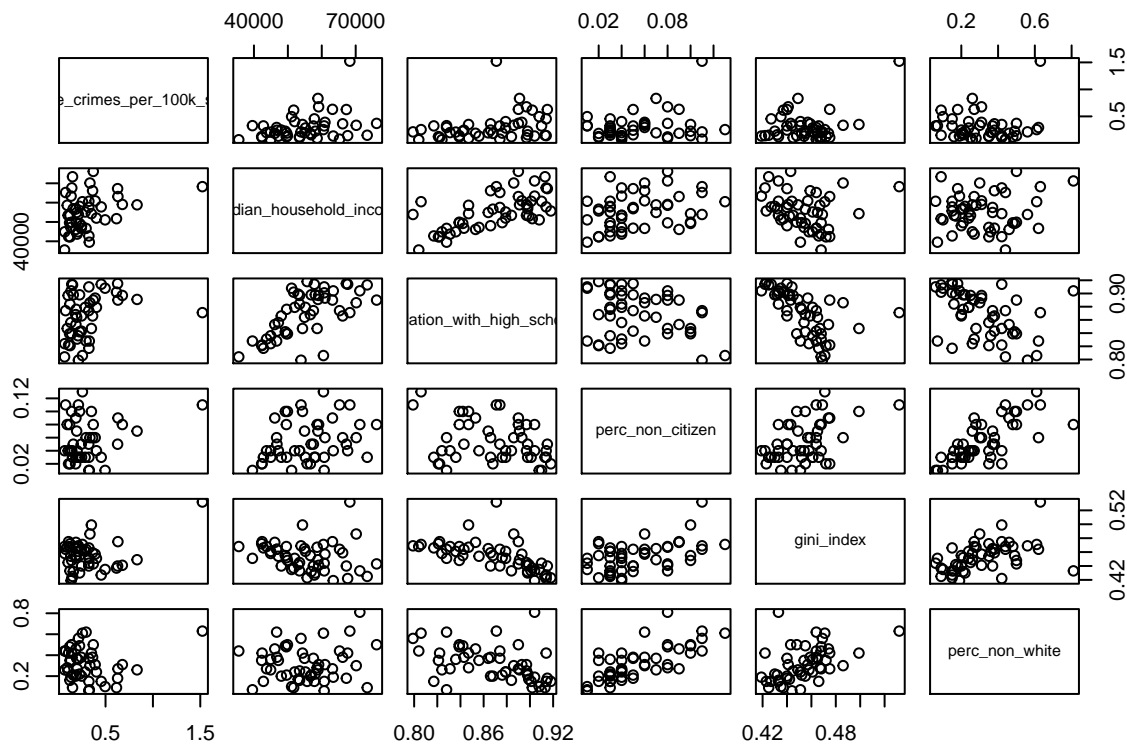

Simple Linear Regression Using Income Inequality (Per FiveThirtyEight)

Fitting SLR using income inequality (measured by Gini index) per FiveThirtyEight findings.

Gini index appears to be a significant predictor only when using the raw outcome data (not the log-transformed outcome data).

Scatter plots associated with these simple linear regression models.

```
hate_df %>%
  ggplot(aes(x = gini_index, y = hate_crimes_per_100k_splc)) +
  geom_point(color = "blue", alpha = 0.6) +
  labs(
    x = "Gini Index",
    y = "Hate Crimes per 100k"
    ) +
  geom_abline(intercept = -1.5275, slope = 4.0205)
```
```
hate_df %>%
  ggplot(aes(x = gini_index, y = log(hate_crimes_per_100k_splc))) +
  geom_point(color = "blue", alpha = 0.6) +
  labs(
    x = "Gini Index",
    y = "Hate Crimes per 100k (Log Scale)"
    ) +
  geom_abline(intercept = -3.676, slope = 4.932)
```
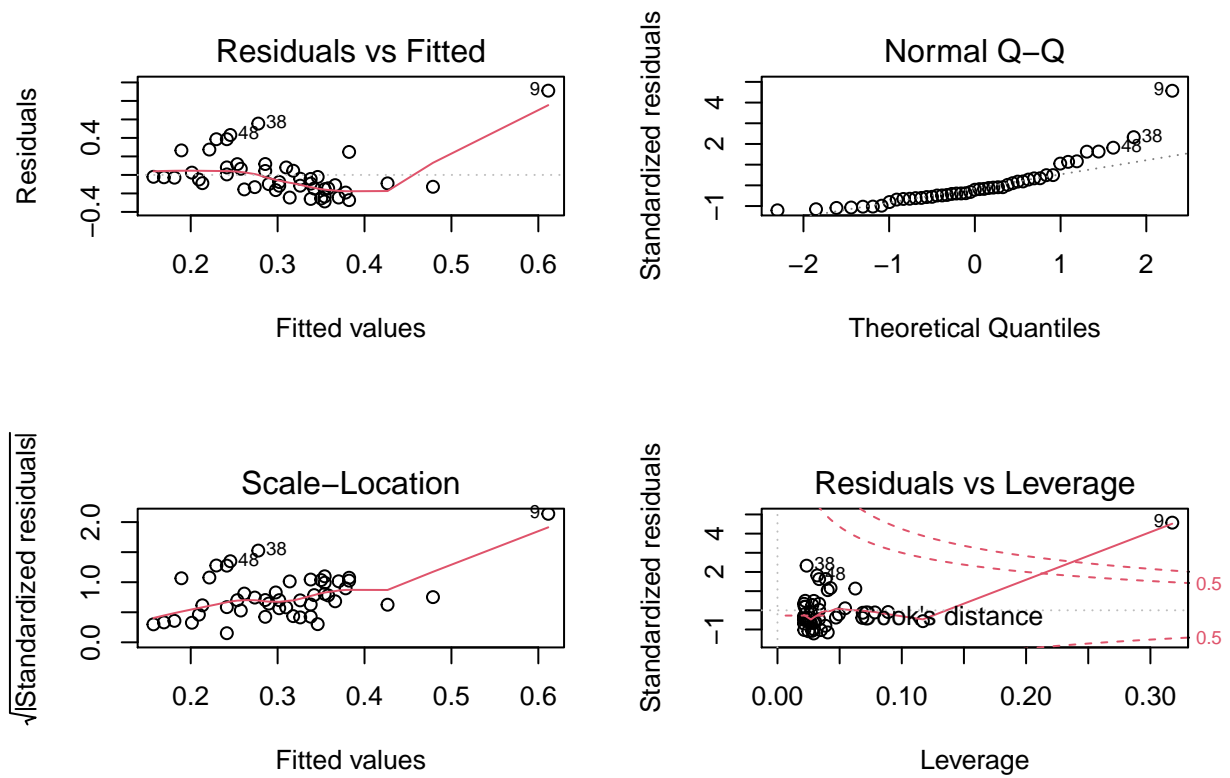

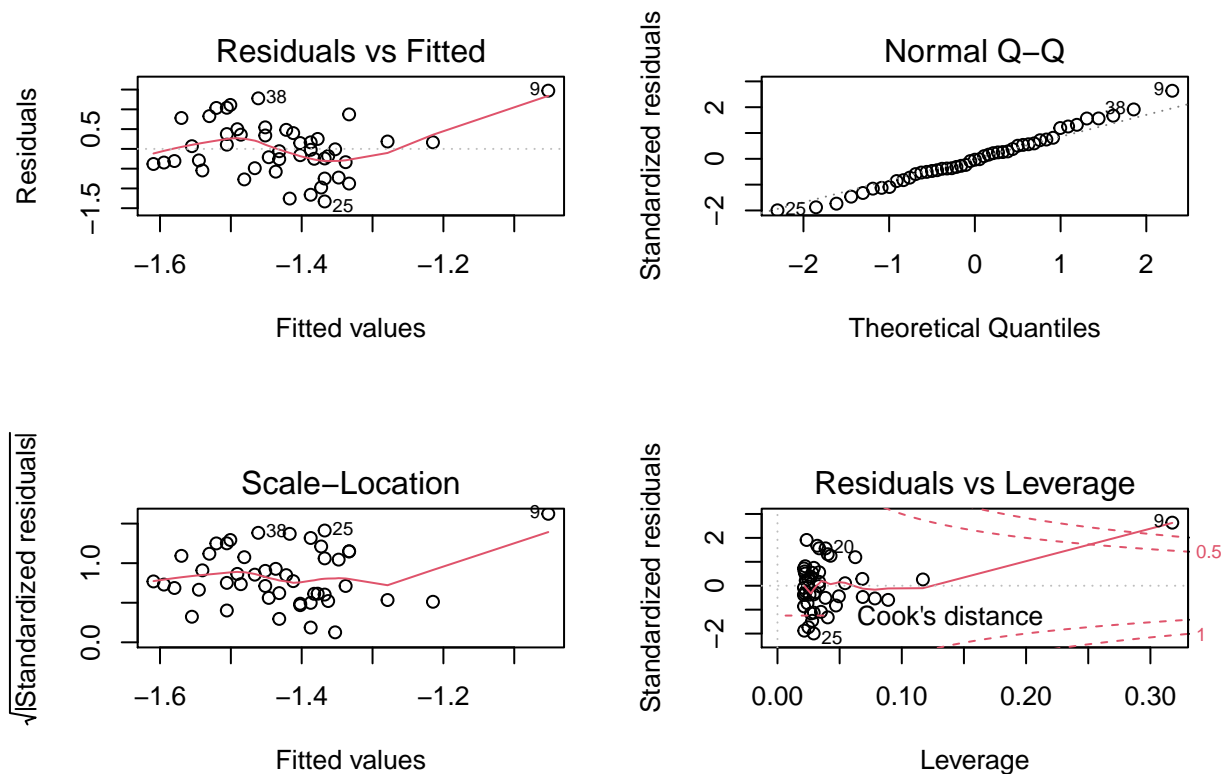

Diagnostic plots of these two simple linear regression models.

```
par(mfrow = c(2, 2))
plot(slr_gini_lm)
```

```r
plot(slr_gini_log_lm)
```

Normality looks better when we perform the log transformation on the outcome data. However, for both versions of this model, we can see an outlying value in the upper right corner (this corresponds to Washington, DC).

Trying Stepwise Approach

First, looking at the full model (with and without log transformation of outcome).

```
hate_nona_df = # Removing rows with missing values from the dataset
  hate_df %>%
  drop_na()

full_lm = lm(
  hate_crimes_per_100k_splc
  ~ unemployment +
    urbanization +
    median_household_income +
    perc_population_with_high_school_degree +
    perc_non_citizen +
    gini_index +
    perc_non_white,
  data = hate_nona_df
)

full_log_lm = lm(
  log(hate_crimes_per_100k_splc)
```

```
    ~ unemployment +
      urbanization +
      median_household_income +
      perc_population_with_high_school_degree +
      perc_non_citizen +
      gini_index +
      perc_non_white,
    data = hate_nona_df
)

summary(full_lm)

}
plot(reg)
```
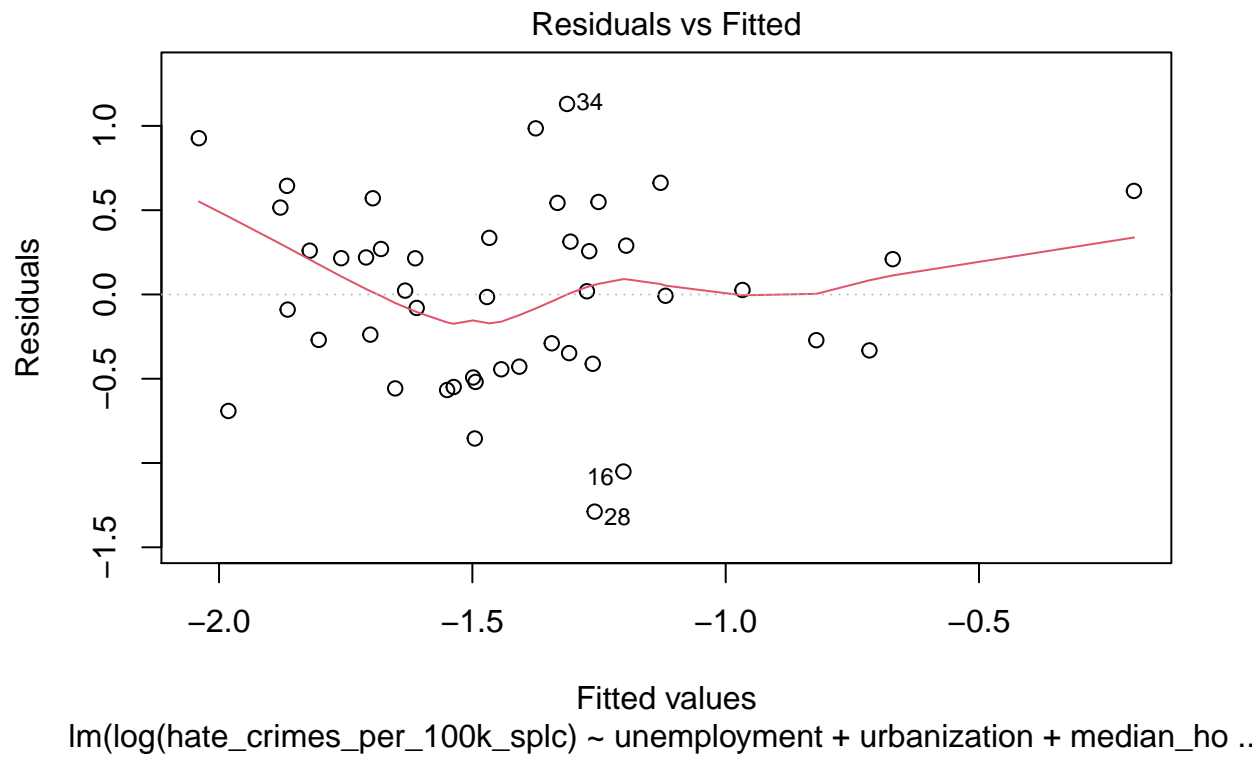

Fit model based on stepwise (log transformed outcome data) and make a scatterplot with regression line, regenerate diagnostic plots using this model

Formalize if DC is an influential point quantitatively using the Cook's value

Using Cook's D and studentized residuals, DC is not a cause for concern. Cook's D is 0.332, not high enough for concern. The studentized residual is not greater than 2.5 for any variable. However, DFFIT is greater than 1. Could be cause for concern. Regression analysis shows it is not influential, so no need to delete.

```r
plot(full_log_lm)
```

Residuals vs Fitted

Fitted values
lm(log(hate_crimes_per_100k_splc) ~ unemployment + urbanization + median_ho ..

Normal Q–Q

Standardized residuals

Theoretical Quantiles
lm(log(hate_crimes_per_100k_splc) ~ unemployment + urbanization + median_ho ..

Scale–Location

√|Standardized residuals|

Fitted values
lm(log(hate_crimes_per_100k_splc) ~ unemployment + urbanization + median_ho ..

Residuals vs Leverage
lm(log(hate_crimes_per_100k_splc) ~ unemployment + urbanization + median_ho ..

Use Box-Cox method

Check for interactions

Fit a linear model with all two-way interactions and investigated the interactions which were significant. There were two where there was a significant interaction between a categorical and continuous variable, between median household income and unemployment, and median household income and urbanization. Looking at the interaction plots between these variables we do see that the lines for the two levels of the categorical variables cross, indicating interaction. Stratifying on unemployment we see that the coefficient for median household income is positive when unemployment is low and negative when unemployment is high. When we stratify on urbanization, we see that the coefficient for median household income has a higher magnitude when urbanization is low (although both coefficients are negative). These stratified analyses

27

indicate that interactions do exist.
